

Drug-specific gain survives centering; context adds complementary signal

What can survive the interaction metric?

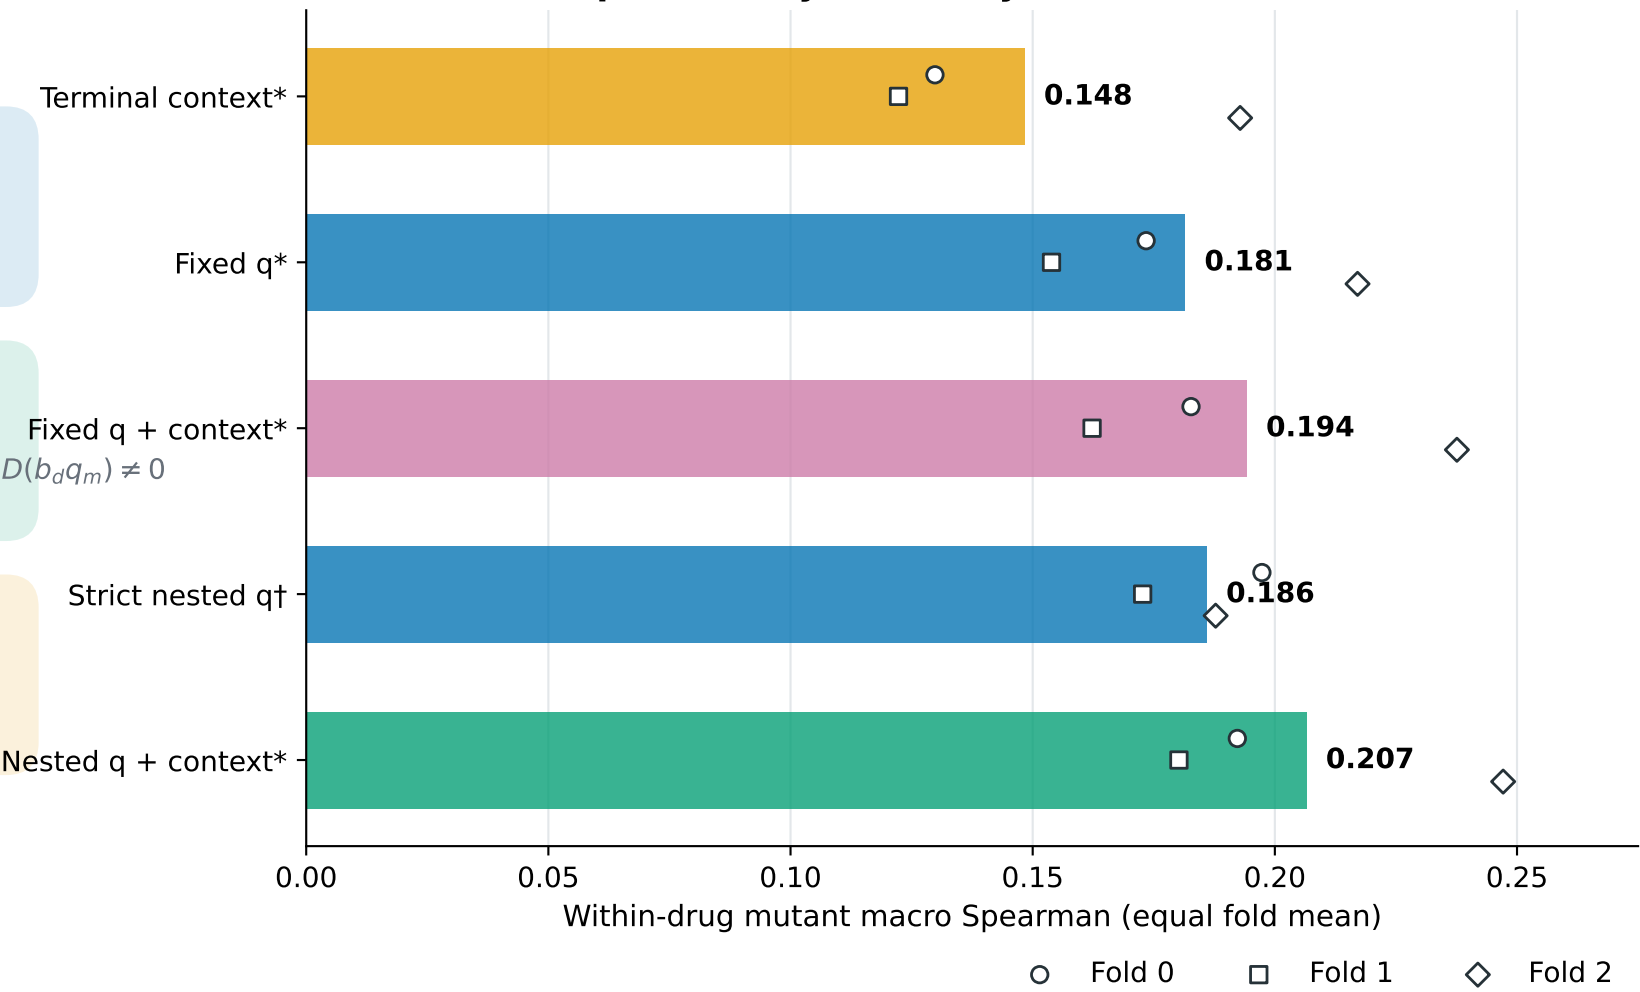

Shared mutation effect q_m
Useful for general response, but $D(q_m) = 0$

Drug-specific gain $b_d q_m$
The same mutation signal can be scaled by drug: $D(b_d q_m) \neq 0$

combine only after
held-fold predictions exist

Context residual r_{md}
Direct mutation-drug information: $D(r_{md}) \neq 0$

Context is complementary, but not yet stable

Terminal hash-bound artifacts; drug is the context and mutant protein is the ranked item
† mechanically strict nested OOF inside the current adaptive study * post-selection diagnostic on the same site folds
